

Problem 1: The Campus Coffee Cart Wallet

A local campus coffee shop wants to eliminate physical punch cards and implement a digital prepaid wallet system for students.

When a student signs up, the system must set up their wallet with their **name** and an **initial opening deposit**.

Throughout the week, students perform transactions:

1. They can **add funds** to their wallet at any time, which should immediately reflect in their total balance.
2. When making a purchase, the system checks whether the wallet has enough funds. If it does, the amount is deducted and the new balance is shown. However, if a student tries to buy a latte that costs more than what is left in their wallet, the transaction must be blocked with an "Insufficient funds!" notice, leaving the balance untouched.
3. At any point, a student can request a **quick account overview** showing their name and current balance.

Your Task:

- Design the CoffeeWallet class to track a customer's wallet.
- In your program's runner (main), simulate a customer opening an account with ₹500, topping up with ₹200, successfully buying a ₹150 snack, and finally attempting an invalid purchase of ₹800.

Problem 2: The Academy Admissions Portal

A coding academy is building an automated student profile manager for its batch admissions.

When a student enrolls, their profile must track their **full name**, **student ID**, and their **final exam score**. However, applicants join under two different scenarios:

- **Exam Takers:** Students who took an entrance evaluation prior to joining provide their name, ID, and their actual score on day one.
- **Direct Walk-ins:** Beginners who haven't taken the entrance test yet register with only their name and ID; their initial score must automatically start at 0.0.

The portal also needs an automated grading engine. When a report card is generated, it should evaluate the student's score and assign a letter grade based on academy criteria:

- **A** for 90 or above
- **B** for scores from 75 up to 89
- **C** for scores from 50 up to 74
- **F** for anything below 50

Your Task:

- Design the StudentProfile class using **two separate constructors** to support both types of enrollments.
- Include a behavior to determine the letter grade and another to print the complete report card (name, ID, score, and grade).
- In main, register one student with a score of 82.5 and another walk-in student with no initial score, then print out both report cards.
